## Results

We present and analyze our results corresponding to our challenges as follows.

### Research direction 1

### Research direction 2

To start, we simulate from OU process. We perform the experiment 4 times for a fixed set of  $\beta_0, \beta_1, \gamma, \mu$ . 200  $X'_t$ s and  $Y'_t$ s without NA are generated in each experiment. We observe that for small values of  $\sigma_{OU}$ , for example 0.00000001, 0.001, 0.01, 0.1, 1, AIC picks Brownian Motion model after parameter inferences are performed. The threshold for AIC to pick the correct model for  $\sigma_{OU}$  lies in somewhere between 1 and  $\sqrt{2}$ .

Similarly, simulate from Brownian Motion process. We perform the experiment 4 times for a fixed set of  $\beta_0, \beta_1$ . 200  $X'_t$ s and  $Y'_t$ s without NA are generated in each experiment.

The above observations match with our intuition on this research direction. As  $\sigma_{OU} \rightarrow 0, \tau \rightarrow 0$ , (todo:equation) becomes  $X_{t+\Delta t}|X_t \sim N(\mu + \omega_{\Delta t}(X_t - \mu))$ , which has the same form as (todo: equation) with a scalar  $\omega_{\Delta t}$  and a shift  $\mu - \omega_{\Delta t}\mu$  applied to  $X_t$ . Thus it is  $X_t$  generated from (todo:equation) can also be interpreted as generated from (todo:equation). Similarly, As  $\sigma_{BM} \rightarrow 0$ , (todo:equation) becomes  $X_{t+\Delta t}|X_t \sim N(X_t, 0)$ , which has the same form as (todo:equation) with  $\tau \rightarrow 0$  or  $\gamma \rightarrow 1$ . Thus it is  $X_t$  generated from (todo:equation) can also be interpreted as generated from (todo:equation).
